Abstract. This paper reviews the synthesis methods of nano titania particles and their utilization in various applications with concise discussion on the related health concerns. Owing to the efficient photocatalytic properties of nano titania particles along with high stability, super hydrophilicity and low cost, these particles are perfect candidate for the production for coatings on the surfaces of construction materials i.e. tiles, facades, wall etc. The nano titania coatings are capable of decomposing dust, dirt and organic pollutants in the presence of sunlight. These decomposed products may then easily be washed away by rinsing thus providing easy cleaning and keeps the buildings in younger or fresh look for decades.

1. INTRODUCTION

Self-cleaning coatings have drawn great interest due to their potential application in many fields of life [1]. The surface cleaning of different building parts like tiles, facades and glass-panes causes an extensive use of energy and costs, which can be minimized to a great extent by using self-cleaning surfaces [2–4]. Two techniques are used to make self-cleaning material surfaces i.e. the development of super-hydrophobic or super-hydrophilic surfaces [3]. Super-hydrophobic surfaces are tremendously repellent to water, owing to a low surface energy of material [5]. In nature, lotus leaves have super-hydrophobic surfaces owing to their waxy low surface energy nature. Whereas, super-hydrophilic surfaces absorb water very quickly e.g. paper, sponges, textiles etc. [2–7]. In construction industry, roads and highways possess very large surface areas that may be modified to get benefits from the self-cleaning and photocatalytic properties of nano titania particles

(NTPs) [8–10]. In the subsequent paras, a brief discussion on the synthesis methodologies of NTPs and afterwards their mechanism of action and applications is provided.

2. SYNTHESIS OF NANO TITANIA PARTICLES (NTPs)

Owing to the potential benefit of NTPs, researchers have investigated vastly the methods for the synthesis and production of nano/micro-TiO₂ structures. Following is a concise summary of methods employed for the synthesis of NTPs.

2.1. Aqueous sol-gel method

The sol-gel method is very famous in materials science for the synthesis of versatile types of materials. In the sol-gel process, a solution is prepared from titanium precursors and suitable solvents. The reactions of hydrolysis and polymerization take

Fig. 1. Typical sol-gel methodology for the synthesis of NTPs, reprinted with permission from S. Winardi, R.R. Mukti, K.N.P. Kumar, J. Wang, W. Wunderlich and T. Okubo // *Langmuir*. 26 (2010) 4567, (c) 2010 American Chemical Society.

place in the solution thus converting the solution into suspension form. In the suspension during the polymerization process the solvents evaporate leading to the formation of gel-like structures. The produced gel may be cast into solid shapes, thin films or coatings and their further heat treatment transforms the gel into a dense and hard material [11–20]. The sol-gel method is so versatile that by controlling the reaction parameters various products ranging from aerogels to ceramic fibers and solid castables to ultrafine powders may be produced [16,17,21–24]. Titania nano particles have been synthesized using various precursors, solvents, catalysts, peptizing and complexing agents under different temperature and aging conditions [17,25,26]. Typical methodology adopted for the synthesis of NTPs via sol-gel process is presented in Fig. 1 [27].

In the sol-gel process, the peptizing agents charge the solution particles; therefore, the electrostatic repulsion among them produces a uniform colloidal suspension without aggregation thus producing smaller size particles in densely packed gel, while in un-peptized solution aggregation starts leading to the larger particle sizes. The particle size and their packing strongly influence the anatase to rutile phase transformation as indicated by Winardi

et al. (Fig. 2) [27]. In the sol-gel process, the molar ratio of water to precursor (W/P) is directly related to the sizes of the titania grains produced and also the small grains produced at lower W/P exhibit lower transformation temperature from anatase to rutile phase. It has been reported that the heat treatment of titania particles increases the particle sizes as well as transformation from anatase to rutile phase but if some dopant (aluminum, tin or iron) are used during the synthesis then the grain sizes during heat treatment do not grow substantially as compared to the undoped sample [26]. Besides powder synthesis, sol-gel process may be used to coat other materials with layers of NTPs as Barmala et al. reported the deposition of thin film and small buds of titania on the surface of MWCNTs when they are added into the hydrolyzed solution of Tetraethyl orthotitanate (TEOT) and isopropanol [28]. The coating formation on multi-walled carbon nanotubes (MWCNTs) increases the surface area of NTPs enormously thus enhancing the photocatalytic efficiency of the NTPs-MWCNTs composite [28].

2.2. Non-aqueous sol-gel method

The sol-gel method may provide better control over the rate of reactions if non-aqueous solvents are

Fig. 2. Influence of peptization on the anatase to rutile phase transformation, reprinted with permission from S. Winardi, R.R. Mukti, K.N.P. Kumar, J. Wang, W. Wunderlich and T. Okubo // *Langmuir*. 26 (2010) 4567, (c) 2010 American Chemical Society.

employed instead of water. In this type of synthesis, the hydrolysis and condensation reactions are much slower as compared to the aqueous sol-gel methods. The slow reactions rates enable the possibility to control over morphology and the size of the NTPs by tuning the reactivity of the precursors [26]. This method may be further be classified in to non-hydrolytic and non-aqueous methods. The prior one is based upon the formation of metal oxides by reaction of oxygen containing organic molecules such as organic ethers or metal alkoxide molecules without any involvement of the water molecules in the process, whereas in the later the water molecules are produced insitu and take part in the hydrolysis [23,29,30]. The synthesis of metal oxides from their chlorides such as titanium tetrachloride (TiCl_4), vanadium oxytrichloride (VOCl_3) and tungsten hexachloride (WCl_6) by using anhydrous benzyl alcohol was firstly reported by Niederberger et al. [31]. The non-aqueous sol-gel method of NTPs synthesis possesses advantage for producing very fine particles with pure crystalline (anatase) phase.

The particle sizes can be controlled by adjusting the amount of precursor, temperature and duration of aging for example lower amount of precursor in the solution produces smaller sized particles whereas higher ageing temperature results in larger particle sizes [32,33]. Another route of NTPs synthesis without any solvent is known as “ether route” in which the precursor and reactants are kept in closed vessels at higher above room temperature. The size and morphology of the developed particles are controlled by the reaction time, temperature and the quantity of precursor and reactant in the mixture [34].

2.3. Hydrothermal and solvothermal method

The photocatalytic activity of the NTPs strongly depends upon their size e.g. NTPs having sizes around 10 nm exhibit much higher rate of photocatalytic action [35,36]. In the sol-gel methods of NTPs, the usual size range of NPs is 20-50 nm.

Fig. 3. FESEM micrographs of NTPs synthesis in hydrothermal process, heating at 80 °C for (a) 30 h, (2) 42 h, (3) 70 h, reprinted with permission from N. Watanabe, T. Kaneko, Y. Uchimaru, S. Yanagida, A. Yasumori and Y. Sugahara // *CrystEngComm*. 15 (2013) 10533, (c) 2013 Royal Society of Chemistry.

Therefore, to obtain the NTPs of very small size hydrothermal method may be employed. The hydrothermal method involves the heating of titanium precursors in peptized or un-peptized form under high temperature and pressures in teflon lined steel autoclaves. The temperature and pressures developed inside the autoclave during the synthesis process strongly depends upon the types and quantity of precursors and additives in the mix. Another advantage of hydrothermal process is that it can produce anatase phase particles in a single step if HCl is used and rutile phase particles in case of HNO_3 as demonstrated by Wu et al. They treated a solution of Tetrabutyl titanate (TBT), HCl and water in a teflon lined vessel for 10 h at 220 °C and synthesized anatase phase particles having average diameter of 10 nm [37]. Watanabe et al. observed that the size of titania particles depends upon the residence time (at the specified temperature) of the precursor solution in the autoclave due to the agglomeration of particles with the passage of time (Fig. 3) [38].

Solvothermal method of NTPs particles synthesis is similar to the hydrothermal except in this procedure water is not utilized in the reaction. The non-aqueous nature of these methods allows the synthesis at even higher temperature and pressure conditions by selecting suitable inorganic solvents having high boiling points and vapor pressures [39]. Wu et al. used the solvothermal process and produced single phase anatase crystals at lower molar ratio of TiCl_4 in the solution whereas rutile fibers at higher concentration of precursor [40]. Their observation about the dependence of particle size on the reaction temperature was in line with the results reported by Jensen and Neiderberger et al. [31–33,40].

2.4. Micelle and reverse micelle method

Micelles are the thermodynamically stable molecular assemblies of the surfactant molecules in a solution. The monomers form agglomerates when their concentrations exceed CMC (critical micelle concentration). In micelles, the monomers consist of hydrophilic heads with long hydrophobic tail. In aqueous solutions, the monomers align themselves into circular micelles with their hydrophobic tails in the center. This aggregation pattern reverse in case of non-polar organic solution and they are referred as inverse or reverse micelles. The shapes of micelles are usually spiral, but also form other shapes depending upon their packing parameters for example surfactant types and their concentrations in the solution [41–45]. Previously, the process of reverse micelles formation has been used for the synthesis of nano, micro and macro sized inorganic particles with effective control on their size and morphology. Besides particles nanowires of BaCO_3 have been synthesized having length of about 100 μm and diameter in the range of 10–30 nm [46]. In reverse micelle method of NTPs synthesis, Sakai et al. reported that the size of NTPs show strong dependence upon the concentration of surfactant molecules in the solution and their size reduces with the increase in the surfactant (Aerosol OT) quantity in the solution [47]. Besides smaller particle sizes at higher concentration of surfactants in solutions produces crystalline phases of anatase or rutile because the surfactant molecules slows down the hydrolysis process therefore giving more time for crystallization [43]. The concentration of acid in the solution also affects the phase composition of the synthesized particles for example at critical con-

Fig. 4. Typical setup of aerosol flame synthesis apparatus.

centration of acid (CCA) in the solution produces crystalline phases of anatase and rutile. The critical quantity of acid depends upon the reaction temperature and reaction media, for example Zhang et al. reported the CCA as 2.5 M in TBT with cyclohexane and NP-5 (Igepal CO-520) whereas Wu et al. evaluated CCA as 1.5 M of HCl in TBT, Triton X-100 and n-hexanol in the temperature range of 120 °C for 12 h and 220 °C for 10 h [37,48]. Sharma et al. investigated the formation of micelle and reverse micelle on the fly ash (FA) core [49]. In the process of micelle formation the sulfate anion of the SDS molecule interact with the FA core shell forming a hydrocarbon chain extending outwards [50]. The titania molecules attracted toward the core shell due to electrostatic potential forming micelles. While in case of using nonionic solution such as Triton X-100 reverse micelle form around the FA core shell in the presence of HCl in the solution as HCl promotes the binding of proton through hydrogen bonding of the Triton X-100 around the core shell [51].

2.5. Aerosol flame synthesis

In this type of synthesis, the titanium precursor solutions are exposed to high temperature flames and due to high temperature, the titanium molecules

react with oxygen to produce NTPs. These particles can be directly deposited as a coating on the solid material sheets or ceramics etc. [52–55]. The typical aerosol flame synthesis setup consists of an aerosol generator and a burner as shown in Fig. 4. The flame coming from the burner is usually stabilized by using ceramic honeycombs. The flame is isolated from the surrounding air with the help of the flow of inert gas around the flame. Falco et al. utilized a TTIP precursor mixed with ethanol to produce NTPs nano particles in the size range of 27–30 nm. The produced phases majorly consisted of rutile because the temperature in the ethylene flame during synthesis may reach up to 1700 °C [56].

Liberini et al. reported that if the concentration of titanium precursor is reduced and synthesis is carried out in lean fuel flame (low temperature as compared to previous one i.e. 1350 °C) then the dominant phase produced is anatase [53,54]. The same phenomena was reported by Makela et al. as shown in Fig. 5 [55].

2.6. Biosynthesis method

This type of synthesis method involves microorganisms such as bacteria (*Bacillus subtilis*, *Lactobacillus* sp., *Klebsiella pneumonia*, *Enterobacteria*, *E.*

coli, *Plectonema boryanum*), yeast (*Saccharomyces cerevisiae*, *Schizosaccharomyces pombe*, *Yarrowia lipolytica*), fungi (*Fusarium oxysporum*, *Verticillium*, *Helminthosporium solani*, *Penicillium fellutanum*, *Hormoconis resinae*, *Trichoderma reesei*) etc. [57–67]. The biosynthesis methods are inexpensive, eco-friendly, scalable, reproducible and non-hazardous. They also do not require toxic substances nor produce harmful byproducts [68,69]. Literature indicates successful application of this method for the synthesis of metal and inorganic nano/micro particles such as gold, silver, CdS, palladium, TiO_2 , Sb_2O_3 , etc.). In the synthesis procedure, the characteristics of the products depends upon the growth of microorganisms and the reaction environment like temperature, pH, minerals and the solution media [58,59,62–65,70]. Therefore, the sizes and shapes of the particles synthesized by this method can be controlled by managing the reaction parameters mentioned above [71,72]. In biosynthesis, the bacteria exhibit strong negative electron potential and subsequently attracts the cations from the solution leading to the processes of

hydrolysis and condensation. In yeasts their membrane (oxidoreductases) activates oxidase at lower pH levels and reductase at higher pH therefore causing the oxidation/reduction process in the biosynthesis whereas fungi are reported to release reducing agents causing the reduction reaction of the ions in the solution as shown in Fig. 6 [71–73]. Bansal et al. reported the synthesis of NTPs by using potassium fluotitanate (K_2TiF_6) as precursor and *Fusarium oxysporum*. The TiF_6^{2-} and the fungi reacted and due the hydrolysis reaction the NTPs were produced [74]. A brief summary of the synthesis of NTPs via methods mentioned above is presented in Table 1.

3. MECHANISM OF PHOTOCATALYSIS OF NTPs

Catalyst is a substance that accelerates a chemical reaction without being consumed. Photocatalysis is the acceleration of a chemical reaction by a catalyst in the presence of light [75]. The idea of application of photocatalysis to environmental

Table 1. Summary of NTPs synthesis methods.

Titanium precursor	Solvent, Surfactants & additives	Synthesis method: Sol-gel method		Crystal phases	Ref.
		Mechanism	Product morphology		
TTIP	Isopropanol, H ₂ O and HNO ₃	Peptized solution heated for 12h at 80 °C and dried at 40 °C	Avg. Particle size 4.53 nm	Anatase	[27]
TEOT	Isopropanol, H ₂ O and HNO ₃	TEOT and alcohol mixture was stirred for 0.5 h and then HNO ₃ was added. MWCNTs added and stirred for 3h and dried after 48 h	Coating and bud formation on MWCNTs	-	[28]
TBT	EtOH, H ₂ O, HCl or AA	The gel was prepared at room temperature and dried in vacuum at 60 °C for 5 h	Avg. Particle size 8.7 nm (fresh) 13.9 nm after 1 y ageing	Anatase	[26]
TBT	Ethylene glycol, acetone	TBT and EG solution was stirred for 8h then acetone added. After 2 h the TiO ₂ particles were separated by centrifugation	203 nm without water addition and 67 nm with water/TBT ratio (v/v) of 50:1	Anatase and rutile	[123]
TTIP	Malonic Acid, Acetic acid, Nitric acid Tri-ethylamine	TTIP and acetic or malonic acid solution was stirred for 30 min then refluxing for 3 h at 100 °C.	Avg. Particle size 52 nm	Anatase with few traces of brookite	[25]
Titanium precursor	Solvent/reactants	Synthesis method: Non-aqueous sol-gel method		Crystal phases	Ref.
		Mechanism	Product morphology		
TiCl ₄	Anhydrous benzyl alcohol	TiCl ₄ and benzyl solution was prepared at 40 °C with continuous stirring. Aging was done for 7-21 days at 40 °C	Particle size 4-8 nm, after calcination 13-20 nm	Anatase	[32]
TiCl ₄	Diisopropyl ether, dichloromethane	Mixture of TiCl ₄ and reactants was kept in pyrex tube at 80 °C for 60 h	Particle size 4-15 nm	80% anatase	[34]
TiCl ₄	Anhydrous benzyl alcohol, ethanol	TiCl ₄ and ethanol solution was prepared then benzyl was added with continuous stirring. Aging was done for 20 and 45 h at 80 °C	Particle size 3-7 nm	Anatase	[33]
TiCl ₄	Acetone	Solution was prepared and heated in sealed teflon vessel for 12 h at 80-140 °C	Particle size 4-10 nm	Anatase at lower TiCl ₄ concentration Rutile fibers at higher TiCl ₄ concentration	[40]

Synthesis method: Hydrothermal and solvothermal method					
Titanium precursor	Surfactants & additives	Mechanism	Product morphology	Crystal phases	Ref.
TTIP	Isopropanol	Calcination in furnace for 1 h at 300 °C under atmospheric pressure	Avg. Particle size 3.89 nm	Anatase	[36]
TBT	H ₂ O, HCl	Calcination of the solution in closed teflon lined furnace for 10 h at 220 °C	Avg. Particle size 10 nm	Anatase	[37]
TiCl ₄	CH ₂ Cl ₂ , UHP	Heating of solution in closed teflon lined vessel for 30, 42 and 70 h at 80 °C	Avg. particle size 5 nm for 30 h heating period	Anatase	[38]
TBT	β-CD, NaOH	Solution of α-CD and H ₂ O was prepared at 60 °C. TBT was added dropwise and homogenized for 2 h. Heating of solution at 150 °C for 48 h in closed teflon lined vessel	Particle size 9-16 nm	Anatase	[124]
Synthesis method: Micelle and reverse micelle method					
Titanium precursor	Surfactants & additives	Mechanism	Product morphology	Crystal phases	Ref.
TTIP	SDS, Ethanol, Fly ash as core shell	Solution stirred for 2 h at room temperature and dried at 50 °C	3-7 nm coating of TiO ₂ on FA particles	Anatase	[49]
TTIP	Triton X-100, HCl, Ethanol, Fly ash as core shell	Solution stirred for 2 h at room temperature and dried at 50 °C	3-7 nm coating of TiO ₂ on FA particles	[101], [200] Anatase[110], [101], [211] Rutile	[49]
TTIP	Aerosol OT, Cyclohexane, Alcohol (2-propanol, 1-butanol, 1-pentanol)	Aerosol OT mixed with cyclohexane at 30 °C for micelle formation then addition of TTIP and alcohol for TiO ₂ particles synthesis	16 nm for 10% concentration of Aerosol OT	Synthesized particles were amorphous but upon calcination at 500°C transformed into Anatase	[47]
TBT	Cyclohexane, NP-5(Igepal CO-520), HCL	Precursor, solvent and surfactant mixed by stirring and standtime of 20 day at RT	35-40 nm width and 150-160 nm long shuttle like structure	At CCA pure rutile were observed and at low acid concentration amorphous or mixture with anatase was produced	[43]

Titanium precursor	Solvent	Synthesis method: Aerosol flame synthesis		Crystal phases	Ref.
		Mechanism	Product morphology		
TTIP	Ethanol	The precursor was heated at 177 °C and introduced into ethylene flame having temp around 1700 °C	Observed particle size 27-30 nm	9-15% anatase and 85-95% rutile	[56]
TTIP	Ethanol	The precursor was introduced in the form of 80 nm droplets into the ethylene flame having temp around 1350 °C and TiO ₂ particles were deposited on aluminium substrate	Average particle size 3.5 nm	Anatase	[53]
TEOT	Ethanol	The solution was injected in H ₂ -O ₂ flame having temp 1100-1500 °C and TiO ₂ particles were deposited on steel substrate	Deposited particle size varied from 5-50 nm with the precursor flow rate 5-200 mg/min (11 nm at 23 mg/min flow)	Anatase at low precursor flow rate and temp and gradually transformation to rutile phase with higher flow rate and temp	[55]
TTIP	Acetonitrile	The solution was introduced into xylene-oxygen flame	Particle size 25-30 nm	96% anatase [011] in oxic flame and 6% anatase in an-oxic flame	[54]
Titanium precursor	Microorganisms	Synthesis method: Bio synthesis method		Crystal phases	Ref.
		Mechanism	Product morphology		
TiO(OH) ₂	Lactobacillus sp.	Culture was grown for 36 h in carbon and nitrogen solution. TiO(OH) ₂ added to diluted culture and heated at 60 °C for 10-20min and kept at RT for 12-48 h	Avg. particle size 24 nm	Anatase and rutile	[71]
TiO(OH) ₂	Sachharomyces cerevisiae	Culture was grown for 36 h in carbon and nitrogen solution. TiO(OH) ₂ added to diluted culture and heated at 60 °C for 10-20 min and kept at RT for 12-48 h	Avg. particle size 12 nm	Anatase and rutile	[71]

K_2TiF_6	Fusarium oxyporum	Culture was grown for 72 h in MGY. K_2TiF_6 added to diluted culture and kept at RT for 24 h	Avg. particle size 10 nm	Rutile and brookite	[74]
------------	-------------------	--	--------------------------	---------------------	------

AA - Acetylacetone $C_5H_8O_2$; AIP - Aluminium isopropoxide; CCA - critical concentration of acid; EtOH - Anhydrous ethanol; FA - Fly ash; FO - Ferric oxide; MWCNTs - Multi wall carbon nano tubes; NPs - Nano particles; NTPs - Nano titania particles; SDS - Sodium dodecyl sulfate; TBT - Tetrabutyl titanate $Ti(O-Bu)_4$ or (Titanium tetra butoxide); TEOT - Tetraethyl orthotitanate or Titanium (IV) ethoxide $Ti(OC_2H_5)_4$; TTCl - Tin tetrachloride; TTIP - Titanium tetra isopropoxide $Ti\{OCH(CH_3)_2\}_4$.

cleanup was given some three decades ago. Titania is found in three crystalline forms: anatase, brookite and rutile. Anatase is reported to exhibit the highest photocatalytic activity [4]. The schematic diagram of photo-catalysis activity is presented in Fig. 7. The light responsible for the photocatalytic effect lies in the Ultra Violet (UV) component of the sunlight spectra. UV is the short-wavelength light after the blue/violet portion of the electromagnetic spectrum (ems). Sun emits light at all the different wavelengths in ems, but it is ultraviolet waves that are responsible for causing sunburns. In the course of action, the NTPs absorb ultraviolet radiation from light and the electron of their valence band transfer into the excited state. The excess energy of this excited electron advances the electron to the conduction band, creating an electron-hole pair. The positive-hole of titanium dioxide breaks apart the water molecule to form hydrogen gas and hydroxyl radical. The negative-electron reacts with oxygen molecule to form superoxide anion. This cycle continues till light is available [4,76].

Fig. 7. Schematic diagram of photo-catalysis activity of NTPs.

The hydroxyl and superoxide radicals are capable of decomposing various organic materials in contact with NTPs surface [75,77]. The airborne pollutant molecules are adsorbed on the NTPs surface and react with these radicals and decomposed. Ideally, the photocatalytic reaction leads to the formation of carbon dioxide (CO_2) and water (H_2O) [75].

4. APPLICATIONS OF NTPs

NTPs are one of the commonly used nano material around the globe (Fig. 8). Physically, it has no absorption in visible light; therefore, it has white color. Chemically, it is stable only in the dark. Its powder form is being used as white pigment since ancient times; it is abundantly available making it an inexpensive material [78]. Its production was approximately 2000 metric tons in 2005, 5000 metric tons in 2010 and expected to reach 10,000 metric tons by 2025 [79–81]. NTPs are mostly used as a white pigment due to its discoloration resistance, brightness and high refractive index; a high amount of NTPs (almost 70% of total generation) is used in paints and coatings [82]. Other items or industries like plastics, paper, textile, food, pharmaceuticals and toothpastes also include a considerable amount [69,83–85]. Some edible items like chocolates, candies and marshmallows also contain NTPs for white color, brightness and flavor [81]. The important industrial applications have also been summarized in Table 2. NTPs provide whitening effects to toothpastes [86]; it was approved as coloring agent in 2002, by food and drug administration (FDA) for use in toothpastes, chewing capsules and mouth fresheners [87]. To achieve improved photo stabilities, NTPs are added in cosmetics [88]. NTPs are considered as ultra-violet resistant material,

Fig. 8. Application areas of NTPs.

Table 2. Industrial applications of NTPs.

Industry	Items	Reasons	Ref.
Paints/ Coatings	Paints, varnishes and polishes	Imparts whiteness, kills germs, exhibits photo-catalysis.	[82,120]
Polymer	Plastics	Provides whiteness, brightness and opacity.	[69,81, 84,91]
Paper	Paper and packaging	Provides whiteness and opacity.	[89]
Cosmetics	Sun screens, whitening and moisture protection creams, makeup powder etc.	Produces milky white color, provides resistant to ultra-violet radiations and does not discolor over a long period of time.	[69,84, 88,120, 125]
Electronics	-	Provides semiconductor properties, catalytic activity, good electrochemical stability Has high dielectric constant and resistance.	[92,109]
Construction Materials	Ceramic materials	Provides thermal stability and acid resistance, having high melting point and high refractive index.	[81]
Textile	All types of cloth	Provides self-cleaning property, wettability, ultra-violet radiations protection, alkali solubility and antimicrobial properties.	[126]
Medicine/ Health	Drug delivery systems and additives in pharmaceuticals	Has antiseptics nature, kills germs and does not immune to corrode by body tissue and fluids.	[69,84, 125,127, 128]
Food	Additives, Beverages, Baked items, Dairy Items, Chocolates etc	Provides whiteness and used as a coloring agent.	[81,86, 87]
Environment	Waste water treatment	Has strong photo-catalyst property, prevents the bacteria to reproduce and causes the organism degradation.	[81,90]

which increases their importance in the production of chemical fibers, printing ink, self-cleaning glass and ceramics [69]. To achieve the opaqueness, NTPs are also used in paper production and food packaging materials [89]. NTPs are also used in antimicrobial applications as well as in air and water purification [79]. Use of NTPs is helpful environmentally as it is a strong photo-catalyst; it can be used to break down complex and harmful organic matters and to kill germs. It can also prevent the bacteria to reproduce and is used as an antiseptic [18,90].

Use of nano NTPs as antifogging agent is also reported due to its extraordinary cleansing properties [81]. NTPs in lambda probes of vehicles is gaining a lot of attention. As it can ensure proper fuel burning and can reduce vehicle emissions leading to clean environment [91]. Efforts are made to remove excess of nitrogen dioxide from environment by using their catalytic properties [69]. Due to higher solar radiation absorption rate, these particles can also be used as thermal and solar photovoltaics to save energy [92]. Properties like good strength, low density, high heat of reaction and corrosion resistance, make the NTPs an excellent materials to be utilized in various industries [93].

Traditional techniques like air purifiers, rather than completely eliminating, transfer the contaminants to another phase: A good method to de-pollute air is to incorporate a photo-catalytic material in the building materials like concrete and mortars [94]. Large surfaces of building materials are often illuminated with either sunlight or electrical lights; the building materials become self-cleaning. Along with cementitious materials, the layers of photo-catalytic material may be deposited on glass panes to make them self-cleaning.

NTPs are well-known photo-catalyst that are used for many anti-pollution activities [19]. NTPs possess photo-catalytic properties because they are able to absorb energy from light, and then utilize it to catalyze the degradation of organic particles and the oxidation of some inorganic pollutants like nitrogen oxides from car exhausts [95]. Being non-toxic, stable and available in huge amounts are the additional qualities that make titania a popular photo-catalytic material [20]. Among many photo-catalysts, titania is reported to have the most efficient photo-activity [78]. Surfaces containing NTPs are in practice in various civil engineering fields e.g. in buildings concrete blocks, plasters, windows and ceramic tiles and in roads in the production of asphalt and road signs [7,96–98]. A brief list of industrial applications of NTPs is presented in Table 2.

5. RELATED HEALTH CONCERNS OF NTPs

Nanomaterial means a natural, incidental or manufactured material, containing particles in an unbound state or as an aggregate or agglomerate; where 50% or more of the particles in the number size distribution have one or more external dimensions in the size range of 1-100 nm [80]. Now days, there is growing trend to use nano/micro materials in all fields of science and technology due to their strong capability of modifying the physical, mechanical properties and producing multifunctional characteristics [99–102]. These nano particles due to their smaller size possess very high penetration capability into the living cells that may produce harmful effects. Conventionally, nano titania particles are considered as low-toxic; however, concerns have been shown on the exposure to NTPs due to high activity and large surface to mass ratio [103]. A lot of researchers reported the health concerns related to NTPs in a very detailed manner [69,104–106]; here a very brief introduction is given.

On the basis of the experimental animal inhalation studies, NTPs are classified as “possible carcinogenic to humans” by the International Agency for Research on Cancer [84,107]. It has been reported that NTPs may cause mild eye irritation; repeated large dosages into the stomach result in some adverse effects to the liver and brain; Consumption of food containing NTPs may cause Crohn’s disease (an inflammatory bowel disease (IBD)) [108,109]. Large quantities inhalation may lead to inflammation and asthma [110,111]. Dermal absorption can be an effective way through which NTPs can enter into human body. Sunscreens and other cosmetic creams can be the source for dermal absorption. However, literature shows that stratum corneum (layer on human skin) prevents the ingress of inorganic particles into human body [2,69]. The superoxide oxygen radicals, Eq. (2), is reported to cause significant damage to DNA [112]. Moreover, cells damage, cellular malfunction and change in proteins amount were also reported by researchers [82,113,114]. NTPs generated reactive oxygen species and oxidative stress, therefore can be considered as toxic [115,116]. Oxidative stress can cause different heart problems and can lead to heart failure [80]. Breathing in large quantities of NTPs over a long period of time may cause toxicity; a study on mice has suggested that low dose (200 mg/kg of body weight (bw)) has no noticeable effect on the reproductive systems, but high-dose (500 mg/kg bw) may significantly reduce their sperm

count and function [117]. Lung and liver tumors were also reported in animals, which were exposed to high concentrations of NTPs [118–120]. In marine organisms NTPs affected the immune and digest gland function [121]. NTPs used in surface coatings are not expected to cause harmful effects to workers if the airborne concentrations be kept below some exposure limit over a period of eight hours. The National Institute for Occupational Safety and Health (NIOSH) in USA has proposed the permissible exposure level (PEL) of 1.5 mg/m³ and a recommended exposure level (REL) of 0.1 mg/m³ [122].

6. CONCLUSIONS

Although the use of nano titania particles is increasing rapidly all over the world. However, it has generated some serious health concerns not only for human but for other living organisms as well. Because of growing applications and large productions, release of NTPs is huge in soil and water bodies. Therefore, it may cause serious threats to human health and ecosystem. Until relevant toxicological and human exposure data that would enable reliable risk assessment are obtained, NTPs should be used with great care.
